1 Modules over a ring

1.1 Modules

Lecture 1 Friday 10/01/20

Let R be an **associative ring with unity**, that is an abelian group written additively with a multiplication which is associative but not necessarily commutative, with an identity 1 and distributive laws a(b+c) = ab + ac and (a+b)c = ac + bc. Then

$$R^* = \{ r \in R \mid \exists s \in R, \ rs = 1 = sr \}$$

is the unit group of R. If $R^* = R \setminus \{0\}$ then R is a **division ring**, or a **skew field**. In the case that R is commutative, R is a **field**.

Example.

- Fields \mathbb{C} , \mathbb{R} , \mathbb{Q} , and \mathbb{F}_q , the field with $q=p^a$ elements with p a prime and $a\geq 1$.
- Skew fields $\mathbb{H} = \{a + bi + cj + dk \mid a, b, c, d \in \mathbb{R}\}$ where $i^2 = j^2 = k^2 = ijk = -1$.
- Other rings are polynomial rings k[x] for k a field, more generally $k[x_1, \ldots, x_p]$, and $\operatorname{Mat}_n k$, the $n \times n$ matrices with entries from k, a field.

Definition 1.1. Let R be a ring. A **left** R-module is an abelian group M, written additively, together with a function $*: R \times M \to M$ satisfying

$$r*(m_1+m_2) = r*m_1+r*m_2, \qquad (r_1+r_2)*m = r_1*m+r_2*m, \qquad (r_1r_2)*m = r_1*(r_2*m), \qquad 1*m = m.$$

We write rm for r * m.

Example.

- R is itself a left R-module, with * as ring multiplication. More generally, let I be a left ideal of R, so I is an additive subgroup, and $rI \subseteq I$ for all $r \in R$. Then I is an R-module with * as ring multiplication.
- Let k be a field. Then any vector space over k is a k-module, and vice versa.
- Any abelian group is a \mathbb{Z} -module, with * defined by $na = a + \cdots + a$ for $n \in \mathbb{Z}^+$ and $a \in A$, and (-n)a = -(na).
- Let k be a field. Let k^n be column vectors. Then k^n is a left $Mat_n k$ -module, with * as the usual matrix-vector multiplication.
- Let $M \in \operatorname{Mat}_n k$. Then we can define a left k[x]-module structure on k^* by letting x act as M on k^* . So $(x^2 + 3x - 2) * v = M^2v + 3Mv - 2v$.
- Let G be a group. Any representation of G over the field k is a left module for k[G], the **group algebra**, a vector space over k with elements of G as a basis, with multiplication derived from that of G.

Definition 1.2. A **right** R**-module** is defined similarly, with the R-multiplication on the right, so M an abelian group under +, and a map $M \times R \to M$ satisfying

$$(m_1 + m_2) * r = m_1 * r + m_2 * r,$$
 $m * (r_1 + r_2) = m * r_1 + m * r_2,$ $m * (r_1 r_2) = (m * r_1) * r_2,$ $m * 1 = m.$

Left and right modules are not quite the same. If we amend this definition by putting the ring multiplication on the left, the third axiom becomes $(r_1r_2) m = r_2 (r_1m)$. But in a left module, we have $(r_1r_2) m = r_1 (r_2m)$.

Definition 1.3. Let R be a ring. The **opposite ring** R^{op} is R with a redefined multiplication $r*_{R^{\text{op}}}s = s*_{R}r$.

It is easy to see that a left R-module is the same as a right R^{op} -module and vice versa. If R is commutative then $R = R^{\text{op}}$.

Exercise. Show that $\operatorname{Mat}_n k \cong \operatorname{Mat}_n k^{\operatorname{op}}$.

Except where otherwise stated, R-modules are assumed to be left R-modules.

Definition 1.4. Let M_1 and M_2 be R-modules. A map $f: M_1 \to M_2$ is an R-module homomorphism if

- \bullet f is a group homomorphism, with respect to the + operation, and
- f(rm) = rf(m), for $r \in R$ and $m \in M$.

If f is bijective, then it is an R-module isomorphism.

Definition 1.5. An additive subgroup $L \leq M$ is a **submodule** if $rL \leq L$ for $r \in R$. In this case we automatically get an R-module structure on the quotient M/L with multiplication given by r(m+L) = rm + L.

Theorem 1.6 (First isomorphism theorem). Let $f: M_1 \to M_2$ be an R-module homomorphism. Then $\operatorname{Im} f \leq M_2$, $\operatorname{Ker} f \leq M_1$, and $\operatorname{Im} f \cong M/\operatorname{Ker} f$.

The other isomorphism theorems have R-module versions too.

Let S be a set. We have a collection of R-modules $(M_s)_S$ indexed by S.

Lecture 2 Monday 13/01/20

Definition 1.7. The direct product is

$$\prod_{s \in S} M_s = \left\{ (m_s)_S \mid m_s \in M_s \right\},\,$$

with coordinate-wise addition and R-multiplication, so

$$(m_s)_S + (n_s)_S = (m_s + n_s)_S$$
, $r(m_s)_S = (rm_s)_S$.

If $M_s = M$ for all $s \in S$, then we write M^S for $\prod_{s \in S} M_s$. The **direct sum** is

$$\bigoplus_{s \in S} M_s = \{(m_s)_S \mid \text{all but finitely many coordinates } m_s \text{ are zero}\} \leq \prod_{s \in S} M_s.$$

If S is finite then the direct product and the direct sum are equal.

Example. Let $M = \mathbb{Z}_2$, as a \mathbb{Z} -module, and let $S = \mathbb{N}$. Then $\bigoplus_{s \in \mathbb{N}} \mathbb{Z}_2$ is a countable \mathbb{Z} -module but $\prod_{s \in \mathbb{N}} \mathbb{Z}_2 = \mathbb{Z}_2^{\mathbb{N}}$ is uncountable.

When |S|=2, generally we write $M_1\oplus M_2$ for the direct sum or product. There are natural injective maps

and surjective maps

1.2 Exact sequences

Definition 1.8. Suppose we have a sequence of R-modules

$$\dots \xrightarrow{f_{n-1}} M_n \xrightarrow{f_n} M_{n+1} \xrightarrow{f_{n+1}} \dots,$$

with maps $f_n: M_n \to M_{n+1}$. Say the sequence is **exact at** M_n if

$$\operatorname{Im} f_{n-1} = \operatorname{Ker} f_n.$$

The sequence is exact if it is exact everywhere. A short exact sequence is an exact sequence

$$0 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 0.$$

Note that α is injective and β is surjective. The first isomorphism theorem implies that $B/\operatorname{Im}\alpha\cong C$, where $\operatorname{Im}\alpha\cong A$. An easy case is

$$B \cong A \oplus C$$
,

with $\operatorname{Im} \alpha = A \oplus 0$ and $\operatorname{Im} \beta = C$, so $\alpha = \iota_A$ and $\beta = \pi_{\beta}$. We say that the short exact sequence **splits** in this case.

Example. A non-split short exact sequence of Z-modules, or abelian groups, is

$$0 \to \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0.$$

Proposition 1.9. A short exact sequence

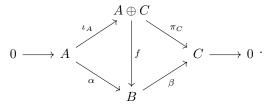

$$0 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 0$$

is split if and only if there exists an R-module homomorphism $\sigma: C \to B$ such that $\beta \circ \sigma = \mathrm{id}_C$.

Such a σ is called a **section** of β .

Proof.

- \implies Suppose that the short exact sequence is split. So assume $B=A\oplus C$, with $\alpha=\iota_A$ and $\beta=\pi_C$. Now ι_C is a section for β .
- \leftarrow For the converse, suppose that σ is a section for β . We want $f: A \oplus C \xrightarrow{\sim} B$ such that $f \circ \iota_A = \alpha$ and $\beta \circ f = \pi_C$, so

Define

$$\begin{array}{ccc} f & : & A \times C & \longrightarrow & B \\ & (a,c) & \longmapsto & \alpha \left(a \right) + \sigma \left(c \right) \end{array}.$$

Need to check the following.

- -f is an R-module homomorphism. ¹
- f is injective. Suppose f(a,c) = 0. Then $\alpha(a) + \sigma(c) = 0$. Now $\alpha(a) \in \text{Im } \alpha = \text{Ker } \beta$, so $\beta(\alpha(a) + \sigma(c)) = \beta(\sigma(c)) = c$. Since $\alpha(a) + \sigma(c) = 0$, we have c = 0. Hence $\alpha(a) = 0$, and so a = 0 since α is injective. We have shown that f is injective.
- f is surjective. Let $b \in B$. Let $c = \beta(b)$. We have $(\beta \circ \sigma)(c) = c = \beta(b)$, so $b \sigma(c) \in \text{Ker } \beta = \text{Im } \alpha$. So there exists $a \in A$ with $\alpha(a) = b \sigma(c)$. Then $b = \alpha(a) + \sigma(c) = f(a, c)$.
- $-f \circ \iota_A = \alpha$ and $\beta \circ f = \pi_C$. Immediate from the construction of f.

Proposition 1.10. The short exact sequence

$$0 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 0$$

is split if and only if there exists $\rho: B \to A$ such that $\rho \circ \alpha = \mathrm{id}_A$.

Such a ρ is a **retraction** of α .

Proof.

- \implies Once again, if the short exact sequence is split then the existence of ρ is clear.
- \Leftarrow Suppose that ρ is a retraction for α . We define $f: B \xrightarrow{\sim} A \oplus C$ such that $f \circ \alpha = \iota_A$ and $\pi_C \circ f = \beta$. Do this by

$$\begin{array}{cccc} g & : & B & \longrightarrow & A \oplus C \\ & b & \longmapsto & (\rho\left(a\right),\beta\left(c\right)) \end{array}.$$

Details are omitted.

¹Exercise

1.3 Projective modules

Definition 1.11. An R-module M is **projective** if any surjective map $\beta: B \to M$ has a section. In other words, any short exact sequence

Lecture 3 Tuesday 14/01/20

$$0 \to A \to B \to M \to 0$$

splits.

Example. The R-module R is projective. Let

$$0 \to A \to B \xrightarrow{\beta} R \to 0$$

be a short exact sequence. Since β is surjective, there exists $b \in B$ such that $\beta(b) = 1$. Now for all $r \in R$, $\beta(rb) = r$. Now define

Then σ is a section for β .

Proposition 1.12. An R-module M is projective if and only if whenever $\beta: B \to C$ is surjective, and $f: M \to C$, there exists $g: M \to B$ such that $f = \beta \circ g$, so

$$0 \longrightarrow A \longrightarrow B \xrightarrow{g} \stackrel{M}{\underset{\beta}{\longleftarrow}} C \longrightarrow 0$$

Such a g is called a **lift** of f.

Proof.

- \Leftarrow Suppose that whenever $\beta: B \to C$ is surjective and $f: M \to C$ then there exists $g: M \to B$ with $f = \beta \circ g$. Suppose $\beta: B \to M$ is a surjective map. Define $f: M \to M$ to be id_M . Then there exists $g: M \to B$ such that $f = \beta \circ g$, so $\mathrm{id}_M = \beta \circ g$. So g is a section for β , and so M is projective.
- \implies For the converse, suppose $\beta: B \to C$ is surjective, and $f: M \to C$. We construct a module X to complete a commuting square

$$X \xrightarrow{\epsilon} M$$

$$\delta \downarrow \qquad \qquad \downarrow f.$$

$$B \xrightarrow{\beta} C$$

Let X be the submodule of $B \oplus M$ defined by

$$X = \{(b, m) \mid \beta(b) = f(m)\}.$$

The maps δ and ϵ are just π_B and π_M respectively, in their restrictions to X. It is clear that $X \leq B \oplus M$, and that the square above commutes. Now suppose that M is projective. Since β is surjective, we see that for all $m \in M$ there exists $b \in B$ with $\beta(b) = f(m)$. It follows that $\epsilon: X \to M$ is surjective. So ϵ has a section $\sigma: M \to X$. Define $g = \delta \circ \sigma: M \to B$, so

$$X \xrightarrow{\epsilon} M$$

$$\delta \downarrow \qquad \qquad \qquad \qquad \downarrow^{\sigma} \qquad \downarrow^{f}.$$

$$B \xrightarrow{\beta} C$$

Since $\beta \circ \delta = f \circ \epsilon$, for all $m \in M$ we have

$$(\beta \circ g)(m) = (\beta \circ \delta \circ \sigma)(m) = (f \circ \epsilon \circ \sigma)(m) = (f \circ id_M)(m) = f(m).$$

So $\beta \circ g = f$ as required.

Such an X is the **pullback** of β and f, and there is a short exact sequence

$$0 \to A \to X \to M \to 0.$$

Definition 1.13. An R-module M is **free** if M is a direct sum of copies of R, so

$$M = \bigoplus_{s \in S} R.$$

A basis for a module M is a set T of elements such that every element $m \in M$ has a unique expression as

$$m = \sum_{i=1}^{m} r_i t_i, \quad r_i \in R, \quad t_i \in T.$$

If $M = \bigoplus_{s \in S} R$, then M has a basis consisting of elements with exactly one coordinate one, and the rest zero. On the other hand, if M has a basis T then it is straightforward to show that $M \cong \bigoplus_{t \in T} R$.

Proposition 1.14. Let F be a free R-module with basis T. Let M be some R-module, and let $\psi: T \to M$ be a set map. Then ψ extends uniquely to a R-module homomorphism $\psi: F \to M$.

Proof. Each element of F has a unique expression as $\sum_i r_i t_i$ for $r_i \in R$ and $t_i \in T$. Now define

$$\psi : F \longrightarrow M \\ \sum_{i} r_{i} t_{i} \longmapsto \sum_{i} r_{i} \psi(t_{i}) .$$

It is easy to check that this respects + and R-multiplication.

Proposition 1.15. A module M is projective if and only if there exists N such that $M \oplus N$ is free, so projective modules are direct summands of free modules.

Proof.

 \implies Suppose M is projective. Let F be the free module with basis $\{b_m \mid m \in M\}$. Now the map $b_m \mapsto m$ extends to an R-module homomorphism $F \to M$, which is clearly surjective. Then if $K = \operatorname{Ker} \psi$, we have a short exact sequence

$$0 \to K \to F \xrightarrow{\psi} M \to 0.$$

Since M is projective, there is a section σ for ψ , and so the short exact sequence splits, and $F \cong K \oplus M$.

Lecture 4 Friday 17/01/20

 \Leftarrow Suppose that $M \oplus N = F$, a free module with basis T. Suppose $\beta : B \to C$ is surjective, and that $f: M \to C$. Note that $f \circ \pi_M : F \to C$. For each $t \in T$, let $b_t \in B$ be such that $\beta(b_t) = (f \circ \pi_M)(t)$. The set map

$$egin{array}{cccc} T & \longrightarrow & E \ t & \longmapsto & b_t \end{array}$$

extends to a homomorphism $\widehat{g}: F \to B$. Now define $g: M \to B$ by $g = \widehat{g} \circ \iota_M$. We need to show $f = \beta \circ g$. Take $m \in M$. Then $\iota_M(m) = (m,0) \in F$ can be written as $\sum_i r_i t_i$, where $t_i \in T$ and $r_i \in R$. Applying π_M , $m = \sum_i r_i m_{t_i}$. Then

$$g(m) = (\widehat{g} \circ \iota_M)(m) = \widehat{g}\left(\sum_i r_i t_i\right) = \sum_i r_i b_{t_i}.$$

So

$$(\beta \circ g)(m) = \beta \left(\sum_{i} r_{i} b_{t_{i}}\right) = \sum_{i} r_{i} \beta(b_{t_{i}}) = \sum_{i} r_{i} f(m_{t_{i}}) = f\left(\sum_{i} r_{i} m_{t_{i}}\right) = f(m).$$

Hence $\beta \circ g = f$. So M is projective.

1.4 Injective modules

Definition 1.16. Let M be an R-module. Then M is **injective** if whenever $\alpha: M \to B$ is an injective map, it has a retraction $\rho: B \to M$, so $\rho \circ \alpha = \mathrm{id}_M$. Equivalently, every short exact sequence

$$0 \to M \to B \to C \to 0$$

splits.

Example. Let k be a field. Then k-modules are vector spaces. Every k-module is injective. Suppose M and N are k-vector spaces and $\alpha: M \to N$ is a injective map. Then $\operatorname{Im} \alpha$ is a submodule, or subspace, of N. Take a basis for $\operatorname{Im} \alpha$, and extend to a basis for N. The basis vectors not in $\operatorname{Im} \alpha$ form a basis for a complementary subspace U, so $N = \operatorname{Im} \alpha \oplus U$. Now $\pi_{\operatorname{Im} \alpha}$ is surjective, and $\alpha: M \to \operatorname{Im} \alpha$ is an isomorphism. This gives a retraction $N \to M$.

If R is a general ring, the module R need not be injective.

Example. Let $R = \mathbb{Z}$. Then R-modules are abelian groups. There exists an injective $\alpha : \mathbb{Z} \to \mathbb{Q}$. But \mathbb{Z} is not a quotient of \mathbb{Q} , 2 so no retraction exists for α .

Proposition 1.17. An R-module M is injective if and only if whenever $\alpha: A \to B$ is injective, and $f: A \to M$, there exists $g: B \to M$ such that $f = g \circ \alpha$.

Proof.

- \Leftarrow Suppose that whenever $\alpha:A\to B$ is injective, and $f:A\to M$, there exists $g:B\to M$ such that $f=g\circ\alpha$. Suppose that $\alpha:M\to B$ is injective. We have a map $M\to M$, namely id_M . There exists $g:B\to M$ such that $\mathrm{id}_M=g\circ\alpha$. So g is a retraction for α , and so M is injective.
- \implies For the converse, suppose $\alpha:A\to B$ is injective, and M is an injective module, with $f:A\to M$. We define a module Y completing a square

$$A \xrightarrow{\alpha} B$$

$$f \downarrow \qquad \qquad \downarrow_{\delta},$$

$$M \xrightarrow{\epsilon} Y$$

with $\epsilon \circ f = \delta \circ \alpha$. Let Y be a quotient of $B \oplus M$, by the kernel

$$K = \{ (\alpha(a), -f(a)) \mid a \in A \}.$$

Let $\gamma: B \oplus M \to (B \oplus M)/K$ be the canonical quotient map. Then we define $\delta = \gamma \circ \iota_B$ and $\epsilon = \gamma \circ \iota_M$. By construction, we have

$$(\epsilon \circ f)(a) = (\gamma \circ \iota_M \circ f)(a) = \gamma(0, f(a)) = (0, f(a)) + K$$

= $(\alpha(a), 0) + K = \gamma(\alpha(a), 0) = (\gamma \circ \iota_B \circ \alpha)(a) = (\delta \circ \alpha)(a).$

Hence $\epsilon \circ f = \delta \circ \alpha$. Claim that ϵ is injective. Suppose $\epsilon(m) = 0$. Then $\iota_M(m) \in K$, so $(0, m) = (\alpha(a), -f(a))$ for some $a \in A$. But $\alpha(a) = 0$ implies that a = 0, and so m = -f(0) = 0. Since M is injective, ϵ has a retraction $\rho: Y \to M$. Define $g: B \to M$ by $g = \rho \circ \delta$, so

$$\begin{array}{c}
A \xrightarrow{\alpha} B \\
f \downarrow \qquad \qquad \downarrow \delta, \\
M \xrightarrow{\xi} Y
\end{array}$$

We know that $(\epsilon \circ f)(a) = (\delta \circ \alpha)(a)$ for all $a \in A$. So

$$f(a) = (\mathrm{id}_M \circ f)(a) = (\rho \circ \epsilon \circ f)(a) = (\rho \circ \delta \circ \alpha)(a) = (g \circ \alpha)(a),$$

so $f = q \circ \alpha$ as required.

²Exercise

We know that projectives are direct summands of free modules. We might hope for a dual version of this for injective modules. But there is no straightforward way of doing this.

Lecture 5 Monday 20/01/20

Proposition 1.18 (Baer's criterion for injectivity). Let M be an R-module. Then M is injective if and only if every R-module map $f: I \to M$, where I is a left ideal of R, has the form f(x) = xm for some $m \in M$. Equivalently, every map $I \to M$ extends to a map $R \to M$.

Why are these two conditions equivalent? If f(x) = xm for $x \in I$, then we can extend f to R by f(r) = rm. Conversely, suppose that $f: I \to M$ extends to $f^+: R \to M$. Let $m = f^+(1)$. Then for all $r \in R$, $f^+(r) = rm$, and so f(x) = xm for $x \in I$. The proof requires Zorn's lemma.

Lemma 1.19 (Zorn's lemma). Let X be a non-empty set, partially ordered by \leq . If every chain, or totally ordered subset, in X has an upper bound in X, then X has a maximal element.

Proof.

 \Leftarrow Suppose $\alpha:A\to B$, where α is injective. Suppose $f:A\to M$. We want to show there exists $g:B\to M$ such that $f=g\circ\alpha$. We have ${\rm Im}\,\alpha\le B$. Define

$$X = \{(L, h) \mid \operatorname{Im} \alpha \leq L \leq B, \ h : L \to M, \ f = h \circ \alpha\}.$$

Note that $X \neq \emptyset$ since $(\operatorname{Im} \alpha, f \circ \alpha^{-1})$ is in it. Define \leq on X by $(L_1, h_1) \leq (L_2, h_2)$ if $L_1 \leq L_2$ and h_2 extends h_1 , so $h_2|_{L_1} = h_1$. Suppose $\{(L_s, h_s) \mid s \in S\}$ is a chain in X. Set $L = \bigcup_{s \in S} L_s$. Then $\operatorname{Im} \alpha \leq L \leq B$. Define

$$\begin{array}{cccc} h & : & L & \longrightarrow & M \\ & l & \longmapsto & h_s\left(l\right) \end{array} , \qquad l \in L_s.$$

This does not depend on the choice of s. Then (L, h) is an upper bound for the chain $\{(L_s, h_s) \mid s \in S\}$. Hence X has a maximal element, (L_0, h_0) . We want to show that $L_0 = B$. Then we may set $g = h_0$. Suppose that $L_0 \neq B$. Let $b \in B \setminus L_0$. Note that $Rb \leq B$. Consider

$$L_0 + Rb = \{l + rb \mid l \in L_0, r \in R\} \le B.$$

We would like to extend h_0 to h_0^+ by specifying an image for h_0^+ (b). The problem is that $Rb \cap L_0$ may not be $\{0\}$, and if $rb \in L_0$ then we require rh_0^+ (b) = h_0 (rb), otherwise h_0^+ will not be well-defined. Note that $I = \{r \in R \mid rb \in L_0\}$ is a left ideal for R. Suppose that M has the condition from Baer's criterion, so every map $I \to M$ has the form $x \mapsto xm$ for some $m \in M$. Note that $\{xb \mid x \in I\}$ is a submodule of L_0 . Define

$$\delta : I \longrightarrow M
 x \longmapsto h_0(xb) .$$

This is an R-module homomorphism. So $\delta(x) = xm$ for some $m \in M$. Hence $h_0(xb) = xm$ for all $x \in I$. So we can safely define $h_0^+(b) = m$. Now $(L_0 + Rb, h_0^+) \in X$, and $(L_0, h_0) < (L_0 + Rb, h_0^+)$, which contradicts the maximality of (L_0, h_0) . Hence $L_0 = B$, and we are done.

 \implies The converse is left as an exercise. ³

Example.

- Suppose R is a field. Then the only ideals of R are zero and R. Any map $0 \to M$, for M an R-module, can be extended to the zero map $R \to M$. Hence any R-module is injective.
- Let \mathbb{Z} be a module for itself. The ideals of \mathbb{Z} are $k\mathbb{Z}$ for $k \in \mathbb{Z}$. Define

$$\begin{array}{cccc} f & : & k\mathbb{Z} & \longrightarrow & \mathbb{Z} \\ & & km & \longmapsto & m \end{array}$$

If $k \neq 0, \pm 1$, then f(k) = 1, and so $f(x) \neq xm$ for $m \in \mathbb{Z}$, since one is not divisible by k in \mathbb{Z} . So Baer's criterion fails, and \mathbb{Z} is not injective. We already knew that $\mathbb{Z} \to \mathbb{Q}$ has no retraction.

• \mathbb{Q} is injective as a \mathbb{Z} -module. Suppose we have a map $f: k\mathbb{Z} \to \mathbb{Q}$. Let q = f(k). Then f(kt) = qt = (q/k) kt. So f(x) = x (q/k) for all x, so \mathbb{Q} satisfies Baer's criterion.

 $^{^3}$ Exercise

1.5 Hom

Let A and B be two R-modules.

Lecture 6 Tuesday 21/01/20

Definition 1.20. Define

$$\operatorname{Hom}_{R}(A, B) = \{R \text{-module homomorphisms } A \to B\}.$$

We can define a natural addition on $\operatorname{Hom}_R(A, B)$ by defining $f_1 + f_2$ by

$$(f_1 + f_2)(a) = f_1(a) + f_2(b), f_1, f_2 \in \operatorname{Hom}_R(A, B).$$

This gives $\operatorname{Hom}_R(A, B)$ the structure of an abelian group. Why does $\operatorname{Hom}_R(A, B)$ not carry an R-module structure in general? The only obvious candidate for rf is

$$(rf)(a) = rf(a) = f(ra), \qquad r \in R, \qquad f \in \operatorname{Hom}_R(A, B).$$

Now suppose $s \in R$. We have (rf)(sa) = rf(sa) = rsf(a). But for rf to be a homomorphism, we would need (rf)(sa) = s(rf)(a) = srf(a). If R is non-commutative, then rs may not be sr, and so rf is not an R-module homomorphism in general. Clearly, however, if R is commutative then rf is an R-module homomorphism, and $Hom_R(A, B)$ has an R-module structure. The following are observations.

Proposition 1.21. Suppose $A, A_1, A_2, B, B_1, B_2, M$ are R-modules, and $\alpha : A \to B$.

- $\operatorname{Hom}_R(A_1 \oplus A_2, B) \cong \operatorname{Hom}_R(A_1, B) \oplus \operatorname{Hom}_R(A_2, B)$.
- $\operatorname{Hom}_R(A, B_1 \oplus B_2) \cong \operatorname{Hom}_R(A, B_1) \oplus \operatorname{Hom}_R(A, B_2)$.
- Then we can define

$$\alpha_* : \operatorname{Hom}_R(M, A) \longrightarrow \operatorname{Hom}_R(M, B)$$
, $f : M \to A$.

• We can also define

$$\begin{array}{cccc} \alpha^{*} & : & \operatorname{Hom}_{R}\left(B,M\right) & \longrightarrow & \operatorname{Hom}_{R}\left(A,M\right) \\ g & \longmapsto & g \circ \alpha \end{array}, \qquad g : B \to M.$$

Thus Hom is a bifunctor between the category of R-modules and the category of abelian groups, additive in both arguments, covariant in the second argument and contravariant in the first argument.

- Bi means Hom takes two arguments.
- \bullet Functor means that homomorphisms between R-modules turn into abelian group homomorphisms.
- Covariant means the homomorphism goes in the same direction.
- Contravariant means the direction gets reversed.
- Additive in both arguments means Hom respects direct sums.

Proposition 1.22. Suppose $\alpha: A \to B$ is surjective. Then $\alpha^*: \operatorname{Hom}_R(B, M) \to \operatorname{Hom}_R(A, M)$ is injective.

Proof. Suppose $f_1, f_2 : B \to M$ are such that $\alpha^*(f_1) = \alpha^*(f_2)$. Then $f_1 \circ \alpha = f_2 \circ \alpha$, so $(f_1 \circ \alpha)(a) = (f_2 \circ \alpha)(a)$ for all $a \in A$. Let $b \in B$. Then $b = \alpha(a)$ for some a, since α is surjective, so $f_1(b) = (f_1 \circ \alpha)(a) = (f_2 \circ \alpha)(a) = f_2(b)$, so $f_1 = f_2$.

Proposition 1.23. Suppose $\alpha: A \to B$ is injective. Then $\alpha_*: \operatorname{Hom}_R(M,A) \to \operatorname{Hom}_R(M,B)$ is injective.

Proof. Suppose $f_1, f_2 : M \to A$, and $\alpha_*(f_1) = \alpha_*(f_2)$. Then $\alpha \circ f_1 = \alpha \circ f_2$, so $(\alpha \circ f_1)(m) = (\alpha \circ f_2)(m)$ for all $m \in M$. But α is injective, so this implies $f_1(m) = f_2(m)$ for all $m \in M$.

Proposition 1.24. Suppose

$$0 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 0$$

is a short exact sequence of R-modules. Then we have an exact sequence

$$0 \to \operatorname{Hom}_{R}(C, M) \xrightarrow{\beta^{*}} \operatorname{Hom}_{R}(B, M) \xrightarrow{\alpha^{*}} \operatorname{Hom}_{R}(A, M)$$
.

Proof. This is exact at $\operatorname{Hom}_R(C, M)$, since β^* is injective. Claim that the sequence is also exact at $\operatorname{Hom}_R(B, M)$, so it is an exact sequence. It is not necessarily a short exact sequence since α^* is not generally surjective. Let $g: B \to M$. We have

$$g \in \operatorname{Ker} \alpha^* \iff \alpha^* \left(g \right) = 0 \iff g \circ \alpha = 0 \iff g \left(\alpha \left(A \right) \right) = 0 \iff \operatorname{Im} \alpha \leq \operatorname{Ker} g \iff \operatorname{Ker} \beta \leq \operatorname{Ker} g,$$

Then $g \in \operatorname{Ker} \alpha^*$ if and only if for all $b_1, b_2 \in B$, $\beta(b_1) = \beta(b_2)$ implies that $g(b_1) = g(b_2)$, which is if and only if the map defined by

$$\begin{array}{cccc} f & : & C & \longrightarrow & M \\ & c & \longmapsto & g\left(b\right) \end{array}, \qquad \beta\left(b\right) = c$$

is well-defined, since β is surjective, and f is an R-module homomorphism. Thus

$$g \in \operatorname{Ker} \alpha^* \iff \exists f \in \operatorname{Hom}_R(C, M), \ \beta^*(f) = g \iff g \in \operatorname{Im} \beta^*$$

Hence $\operatorname{Ker} \alpha^* = \operatorname{Im} \beta^*$. So the sequence is exact at $\operatorname{Hom}_R(B, M)$.

Lecture 7 Friday 24/01/20

Example. These examples show that $\alpha:A\to B$ is injective does not imply $\alpha^*:\operatorname{Hom}_R(B,M)\to \operatorname{Hom}_R(A,M)$ is surjective.

• The inclusion $\alpha : \mathbb{Z} \to \mathbb{Q}$ is a \mathbb{Z} -module homomorphism. Let $M = \mathbb{Z}$. Then we get $\alpha^* : \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Q}, \mathbb{Z}) \to \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z})$. Then α is injective, but α^* is not surjective. Why is this? In fact $\operatorname{Hom}_{\mathbb{Z}}(\mathbb{Q}, \mathbb{Z}) = 0$. Suppose

$$f : \mathbb{Q} \longrightarrow \mathbb{Z} \\ 1 \longmapsto k \neq 0 .$$

Suppose $p \nmid k$. Then there is no possible image for $1/p \in \mathbb{Q}$, since we would require pf(1/p) = f(1) = k. But $\text{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z}) \cong \mathbb{Z}$, so α^* is not surjective.

• Let $\alpha: k\mathbb{Z} \to \mathbb{Z}$ be the inclusion, so α is injective and not surjective. Let $M = \mathbb{Z}$. So we get $\alpha^*: \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z}) \to \operatorname{Hom}_{\mathbb{Z}}(k\mathbb{Z}, \mathbb{Z})$. Suppose that $g \in \operatorname{Im} \alpha^*$. Then $g = f \circ \alpha$, where $f: \mathbb{Z} \to \mathbb{Z}$. Then g(k) = f(k) = kf(1), so $\operatorname{Im} g \leq k\mathbb{Z}$. But there exists $g \in \operatorname{Hom}_{\mathbb{Z}}(k\mathbb{Z}, \mathbb{Z})$ such that g(k) = 1. So this $g \notin \operatorname{Im} \alpha^*$, so α^* is not surjective.

Proposition 1.25. Let

$$0 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 0$$

be exact. Then

$$0 \to \operatorname{Hom}_{R}\left(M,A\right) \xrightarrow{\alpha_{*}} \operatorname{Hom}_{R}\left(M,B\right) \xrightarrow{\beta_{*}} \operatorname{Hom}_{R}\left(M,C\right)$$

is exact.

Proof. We already know that α injective implies that α_* is injective, so the sequence is exact at $\operatorname{Hom}_R(M, A)$. We show that $\operatorname{Ker} \beta_* = \operatorname{Im} \alpha_*$. Suppose $g \in \operatorname{Hom}_R(M, B)$. Then

$$g\in\operatorname{Ker}\beta_{*}\qquad\iff\qquad\left(\beta\circ g\right)\left(M\right)=0\qquad\iff\qquad\operatorname{Im}g\leq\operatorname{Ker}\beta\qquad\iff\qquad\operatorname{Im}g\leq\operatorname{Im}\alpha.$$

Note there exists $\alpha^{-1}: \operatorname{Im} \alpha \to A$. If $\operatorname{Im} g \leq \operatorname{Im} \alpha$, then $\alpha^{-1} \circ g: M \to A$. If $f = \alpha^{-1} \circ g$, then $\alpha \circ f = g$, so $g \in \operatorname{Im} \alpha_*$. Conversely, if $g \in \operatorname{Im} \alpha_*$, then $g = \alpha \circ f$ for some $f \in \operatorname{Hom}_R(M, A)$ and so $\operatorname{Im} g \leq \operatorname{Im} \alpha$. So

$$g \in \operatorname{Ker} \beta_* \iff \operatorname{Im} g \leq \operatorname{Im} \alpha \iff g \in \operatorname{Im} \alpha_*$$

Hence $\operatorname{Ker} \beta_* = \operatorname{Im} \alpha_*$. So the sequence is exact at $\operatorname{Hom}_R(M, B)$.

Example. These examples show that $\beta: B \to C$ is surjective does not imply $\beta_*: \operatorname{Hom}_R(M, B) \to \operatorname{Hom}_R(M, C)$ is surjective.

• Let

$$\beta : \sum_{q \in \mathbb{Q}} \mathbb{Z} \longrightarrow \mathbb{Q}$$

$$e_q \longmapsto q .$$

In general $\beta: \sum_{m\in M} R \to M$ defined by mapping the basis vector e_m to m, is a surjective homomorphism, so β is surjective. Let $M=\mathbb{Q}$. So we get $\beta_*: \operatorname{Hom}_{\mathbb{Z}}\left(\mathbb{Q}, \sum_{q\in\mathbb{Q}}\mathbb{Z}\right) \to \operatorname{Hom}_{\mathbb{Z}}\left(\mathbb{Q}, \mathbb{Q}\right)$. Claim that $\operatorname{Hom}_{\mathbb{Z}}\left(\mathbb{Q}, \sum_{q\in\mathbb{Q}}\mathbb{Z}\right)$ is trivial. Suppose $f:\mathbb{Q}\to\sum_{q\in\mathbb{Q}}\mathbb{Z}$ is not zero. Suppose $f(q_0)\neq 0$. Then there exist $q_1,\ldots,q_t\in\mathbb{Q}$ and $a_1,\ldots,a_t\in\mathbb{Z}$ such that $f(q_0)=\sum_{i=1}^t a_i e_{q_i}$. Now the projection of $\sum_{q\in\mathbb{Q}}\mathbb{Z}$ onto $\mathbb{Z}e_{q_1}$ is a non-trivial \mathbb{Z} -module homomorphism. But $\mathbb{Z}e_{q_1}\cong\mathbb{Z}$, and so no non-trivial map $\mathbb{Q}\to\mathbb{Z}e_{q_1}$ exists. But $\operatorname{Hom}_{\mathbb{Z}}\left(\mathbb{Q},\mathbb{Q}\right)$ is not trivial, so β_* is not surjective.

• Let

$$0 \to \mathbb{Z}_2 \to \mathbb{Z}_4 \to \mathbb{Z}_2 \to 0$$

be a short exact sequence of \mathbb{Z} -modules. Then we have

But there is no short exact sequence of abelian groups

$$0 \to \mathbb{Z}_2 \to \mathbb{Z}_2 \to \mathbb{Z}_2 \to 0,$$

and so β_* cannot be surjective.

Proposition 1.26. Let M be an R-module. Then M is injective if and only if for every injective map $\alpha: A \to B$, we get $\alpha^*: \operatorname{Hom}_R(B, M) \to \operatorname{Hom}_R(A, M)$ is surjective.

Proof. M is injective if and only if for all injective $\alpha: A \to B$, for all $f \in \operatorname{Hom}_R(A, M)$, there exists $g \in \operatorname{Hom}_R(B, M)$ such that $f = g \circ \alpha$, so $f = \alpha^*(g)$. This is if and only if for all injective $\alpha: A \to B$, $f \in \operatorname{Im} \alpha^*$ for all $f \in \operatorname{Hom}_R(A, M)$, which is if and only if α^* is surjective.

Proposition 1.27. Let M be an R-module. Then M is projective if and only if whenever $\beta: B \to C$ is surjective, the map $\beta_*: \operatorname{Hom}_R(M, B) \to \operatorname{Hom}_R(M, C)$ is surjective.

Proof. M is projective if and only if whenever $\beta: B \to C$ is surjective, and $f \in \operatorname{Hom}_R(M, C)$, there exists $g \in \operatorname{Hom}_R(M, B)$ such that $f = \beta \circ g$. This is if and only if whenever $\beta: B \to C$ is surjective, and $f \in \operatorname{Hom}_R(M, C)$, then $f \in \operatorname{Im} \beta_*$, which is if and only if β_* is surjective.

1.6 The snake lemma

Let $\alpha:A\to B$ be an R-module homomorphism. The **cokernel** of α is $B/\operatorname{Im} \alpha$, written $\operatorname{Coker} \alpha$. The sequence

Lecture 8 Monday 27/01/20

$$0 \to \operatorname{Ker} \alpha \to A \xrightarrow{\alpha} B \to \operatorname{Coker} \alpha \to 0$$

is exact.

Lemma 1.28 (The snake lemma). Suppose we have a commutative diagram

where the rows are exact. Then we obtain an exact sequence

$$\operatorname{Ker} f \xrightarrow{\overline{\alpha}} \operatorname{Ker} g \xrightarrow{\overline{\beta}} \operatorname{Ker} h \xrightarrow{\delta} \operatorname{Coker} f \xrightarrow{\overline{\phi}} \operatorname{Coker} g \xrightarrow{\overline{\psi}} \operatorname{Coker} h.$$

Proof.

• The maps $\overline{\alpha}$: Ker $f \to \text{Ker } g$ and $\overline{\beta}$: Ker $g \to \text{Ker } h$ are obtained simply by restricting α and β respectively. Observe that if $a \in \text{Ker } f$ then f(a) = 0, so $(\phi \circ f)(a) = 0$. But $\phi \circ f = g \circ \overline{\alpha}$, and so $(g \circ \overline{\alpha})(a) = 0$, so $\overline{\alpha}(a) \in \text{Ker } g$, which is what we wanted.

• The maps $\overline{\phi}$: Coker $f \to \operatorname{Coker} g$ and $\overline{\psi}$: Coker $g \to \operatorname{Coker} h$ are induced from ϕ and ψ by

$$\overline{\phi}(x + \operatorname{Im} f) = \phi(x) + \operatorname{Im} g, \qquad \overline{\psi}(y + \operatorname{Im} g) = \psi(g) + \operatorname{Im} h.$$

Check that these maps make sense. Suppose $x_1 + \text{Im } f = x_2 + \text{Im } f$. Then $x_1 - x_2 \in \text{Im } f$, so there exists $a \in A$ such that $f(a) = x_1 - x_2$. Now

$$\phi(x_1) - \phi(x_2) = \phi(x_1 - x_2) = (\phi \circ f)(a) = (g \circ \alpha)(a) \in \text{Im } g.$$

So $\phi(x_1) + \text{Im } g = \phi(x_2) + \text{Im } g$. So $\overline{\phi}$ is well-defined, and $\overline{\psi}$ is shown to be well-defined by a similar argument.

• How is the **connecting homomorphism** δ defined? Since β is surjective, for all $c \in C$, there exists $b \in B$ with $\beta(b) = c$. Suppose $c \in \text{Ker } h$. Then $(h \circ \beta)(b) = 0$, so $(\psi \circ g)(b) = 0$. Hence $g(b) \in \text{Ker } \psi = \text{Im } \phi$. Define

$$\delta(c) = x + \operatorname{Im} f, \qquad \phi(x) = g(b), \qquad \beta(b) = c.$$

Check this is well-defined. Suppose b_1, b_2, x_1, x_2 are such that $\phi(x_1) = g(b_1)$ and $\phi(x_2) = g(b_2)$, and $\beta(b_1) = \beta(b_2) = c$. We have $b_1 - b_2 \in \text{Ker } \beta = \text{Im } \alpha$. So $b_1 - b_2 = \alpha(a)$ for some $a \in A$. Then

$$(\phi \circ f)(a) = (g \circ \alpha)(a) = g(b_1 - b_2) = g(b_1) - g(b_2) = \phi(x_1) - \phi(x_2) = \phi(x_1 - x_2).$$

But ϕ is injective, and so $f(a) = x_1 - x_2$, and so $x_1 + \operatorname{Im} f = x_2 + \operatorname{Im} f$. So δ is well-defined.

Exactness of the sequence is an exercise, on problem sheet.

1.7 Tensor products

Definition 1.29. Let M be a left R-module, and let L be a right R-module. The **tensor product** $L \otimes_R M$ is an abelian group generated as an abelian group by a set of **pure tensors**

$$\{l \otimes m \mid l \in L, m \in M\},\$$

subject to the relations

$$l_1 \otimes m + l_2 \otimes m = (l_1 + l_2) \otimes m, \qquad l_1, l_2 \in L, \qquad m \in M,$$

$$l \otimes m_1 + l \otimes m_2 = l \otimes (m_1 + m_2), \qquad l \in L, \qquad m_1, m_2 \in M,$$

$$(lr) \otimes m = l \otimes (rm), \qquad l \in L, \qquad m \in M, \qquad r \in R.$$

The following are observations.

- In general, not every element of $L \otimes_R M$ is a pure tensor. A general element of $L \otimes_R M$ is a \mathbb{Z} -linear combination of pure tensors.
- If R is commutative, L can be a left module, since left and right modules are the same. Also, in this case, $L \otimes_R M$ has an R-module structure, by $r(l \otimes m) = rl \otimes m$.
- Suppose that S is a set of generators for L, as an abelian group, and T is a set of generators for M, as an abelian group. Then a smaller generating set for $L \otimes_R M$ is $\{s \otimes t \mid s \in S, t \in T\}$. This is because if

$$l = \sum_{i=1}^{p} a_i s_i, \qquad m = \sum_{i=1}^{q} b_j t_j, \qquad s_i \in S, \qquad t_i \in T, \qquad a_i, b_i \in \mathbb{Z},$$

then, from the relations,

$$l \otimes m = \sum_{i=1}^{p} \sum_{j=1}^{q} a_i b_j s_i \otimes t_j.$$

Example. Tensor products can be counter intuitive, such as $\mathbb{Z}_2 \otimes_{\mathbb{Z}} \mathbb{Z}_3 = 0$. Why? Observe that for $x \in \mathbb{Z}_2$, x3 = 3x = x. So for all $x \in \mathbb{Z}_2$ and $y \in \mathbb{Z}_3$,

$$x \otimes y = x3 \otimes y = x \otimes 3y = x \otimes 0 = x \otimes y - x \otimes y = 0.$$

Lecture 9 Tuesday 28/01/20

Theorem 1.30 (Universal property of tensor products). Let A be a right R-module and B a left R-module. Let C be an abelian group. Let $f: A \times B \to C$ be a map, not necessarily a homomorphism, which is \mathbb{Z} -linear in both arguments, so

$$f(a_1 + a_2, b) = f(a_1, b) + f(a_2, b),$$
 $a_1, a_2 \in A,$ $b \in B,$
 $f(a, b_1 + b_2) = f(a, b_1) + f(a, b_2),$ $a \in A,$ $b_1, b_2 \in B,$

and such that

$$f(ar, b) = f(a, rb), \qquad a \in A, \qquad b \in B, \qquad r \in R.$$

Then there is a unique homomorphism

$$g : A \otimes_R B \longrightarrow C$$
$$a \otimes b \longmapsto f(a,b) .$$

Proof. In formal group theoretic terms, the tensor product $A \otimes_R B$ is a quotient F/K, where F is the free abelian group on the set of pure tensors $a \otimes b$, and K is the subgroup of F generated by elements of the form

$$(a_1 + a_2) \otimes b - a_1 \otimes b - a_2 \otimes b,$$
 $a \otimes (b_1 + b_2) - a \otimes b_1 - a \otimes b_2,$ $ar \otimes b - a \otimes rb.$

The universal property of free abeian groups states that if F is free abelian on a set S, then any set map $S \to C$, for C an abelian group, extends uniquely to a homomorphism $F \to C$. In the situation under discussion, we have a map

$$g': \{a \otimes b \mid a \in A, b \in B\} \to C.$$

So g' extends uniquely to a homomorphism $F \to C$. The conditions stipulated on f guarantee that g'(K) = 0. So g' induces a map $g: F/K \to C$, which is what we want, since $F/K = A \otimes_R B$. This establishes the existence of g. Since the images of the pure tensors under g are specified, it is clear that g is unique.

Corollary 1.31.

1. Let M be a left R-module. Then $R \otimes_R M \cong M$, via the map

$$\begin{array}{ccccc} f & : & M & \longrightarrow & R \otimes_R M \\ & & m & \longmapsto & 1 \otimes m \end{array}.$$

2. Let M be a right R-module. Then $M \otimes_R R \cong M$.

Proof.

1. It is clear that f is a homomorphism of abelian groups. Now $r \otimes m = 1 \otimes rm$, so $R \otimes_R M$ is generated by $\{1 \otimes m \mid m \in M\}$, so f is surjective. For injectivity of f, we need the universal property. Define a bilinear map

$$\begin{array}{ccc} R\times M & \longrightarrow & M \\ (r,m) & \longmapsto & rm \end{array}.$$

This induces a homomorphism

It is easy to check that g is an inverse for f, so f is bijective.

2. By the same argument as 1.

Corollary 1.32. Let A and B be right R-modules, and let C be a left R-module.

1. $(A \oplus B) \otimes_R C \cong (A \otimes_R C) \oplus (B \otimes_R C)$, via the map

$$f : (A \oplus B) \otimes_R C \longrightarrow (A \otimes_R C) \oplus (B \otimes_R C)$$
$$(a,b) \otimes c \longmapsto (a \otimes c,b \otimes c)$$

2. $A \otimes_R (B \oplus C) \cong (A \otimes_R B) \oplus (A \otimes_R C)$.

Proof.

1. Take a bilinear map, that is \mathbb{Z} -bilinear in both arguments, and respecting R-multiplication,

$$\begin{array}{ccc} A \oplus B \times C & \longrightarrow & (A \otimes_R C) \oplus (B \otimes_R C) \\ ((a,b),c) & \longmapsto & (a \otimes c,b \otimes c) \end{array}.$$

This induces a homomorphism $f:(A \oplus B) \otimes_R C \to (A \otimes_R C) \oplus (B \otimes_R C)$ with the description as given above. Now take the bilinear map given by

$$\begin{array}{ccc} A \times C & \longrightarrow & (A \oplus B) \otimes_R C \\ (a,c) & \longmapsto & (a,0) \otimes c \end{array}$$

This induces a homomorphism $g_1:A\otimes_R C\to (A\oplus B)\otimes_R C$. Similarly, we get a homomorphism $g_2:B\otimes_R C\to (A\oplus B)\otimes_R C$. Now define

$$g = g_1 \oplus g_2$$
 : $(A \otimes_R C) \oplus (B \otimes_R C) \longrightarrow (A \oplus B) \otimes_R C$
 $(x,y) \longmapsto g_1(x) + g_2(y)$

It is easy to check that f and g are mutually inverse, so both isomorphisms.

2. Similarly.

Corollary 1.33. Let A be an abelian group. Then

- 1. $\mathbb{Z}_n \otimes_{\mathbb{Z}} A \cong A/nA$, and
- 2. $A \otimes_{\mathbb{Z}} \mathbb{Z}_n \cong A/nA$.

Proof.

1. Define a map by

$$\begin{array}{cccc} f & : & A & \longrightarrow & \mathbb{Z}_n \otimes_{\mathbb{Z}} A \\ & & a & \longmapsto & 1 \otimes a \end{array}.$$

Suppose $a_0 \in A$ such that $a_0 = na$ for some a. Then $f(a_0) = 1 \otimes a_0 = 1 \otimes na = n \otimes a = 0$ so $nA \leq \text{Ker } f$. So f induces a map

$$\overline{f}: A/nA \to \mathbb{Z}_n \otimes_{\mathbb{Z}} A.$$

Notice that the pure tensor $k \otimes a$ is equal to $1 \otimes ka$, so $\mathbb{Z}_n \otimes_{\mathbb{Z}} A$ is generated by $\{1 \otimes a \mid a \in A\}$. So \overline{f} is surjective. For injectivity, use the universal property. We have a bilinear map

$$g : \mathbb{Z}_n \times A \longrightarrow A/nA \\ (k,a) \longmapsto ka + nA .$$

This is well-defined and bilinear. So extends to a homomorphism

$$\overline{q}: \mathbb{Z}_n \otimes_{\mathbb{Z}} A \to A/nA.$$

It is easy to check that $\overline{q} \circ \overline{f} = \mathrm{id}_{A/nA}$, so \overline{f} is injective.

2. Similarly.

Proposition 1.34. Let $\alpha: A \to B$ be a homomorphism of right R-modules. Let M be a left R-module. There is a unique abelian group homomorphism

Lecture 10 Friday 31/01/20

Proof. The set map defined by

$$\begin{array}{cccc} f & : & A \times M & \longrightarrow & B \otimes_R M \\ & & (a,m) & \longmapsto & \alpha(a) \otimes m \end{array}$$

is linear in both arguments, and we have

$$f(ar, m) = \alpha(ar) \otimes m = \alpha(a) r \otimes m = \alpha(a) \otimes rm = f(a, rm).$$

Now by the universal property of tensor products, f gives rise to a unique homomorphism $\alpha': A \otimes_R M \to B \otimes_R M$ with the properties claimed.

Proposition 1.35. Suppose $\alpha: A \to B$ is surjective. Then $\alpha': A \otimes_R M \to B \otimes_R M$ is surjective.

Proof. Since α is surjective, every pure tensor $b \otimes m \in B \otimes_R M$ is equal to $\alpha(a) \otimes m$ for some $a \in A$. So $b \otimes m = \alpha'(a \otimes m) \in \operatorname{Im} \alpha'$. Since $B \otimes_R M$ is generated by its pure tensors, α' is surjective.

An observation is that it is not true that $A \to B$ is injective implies $A \otimes_R M \to B \otimes_R M$ is injective.

Example. Let

$$\alpha : \mathbb{Z}_2 \longrightarrow \mathbb{Z}_4,$$

$$1 \longmapsto 2,$$

which is injective. Consider

$$\alpha'$$
: $\mathbb{Z}_2 \otimes_{\mathbb{Z}} \mathbb{Z}_2 \cong \mathbb{Z}_2 \longrightarrow \mathbb{Z}_4 \otimes_{\mathbb{Z}} \mathbb{Z}_2$
 $1 \otimes 1 \longmapsto 2 \otimes 1 = 1 \otimes 2 = 0$.

So α' is the zero map, which is not injective.

Proposition 1.36. Let

$$0 \to A \xrightarrow{\alpha} B \xrightarrow{\beta} C \to 0$$

be a short exact sequence of right R-modules. Then the sequence

$$A \otimes_R M \xrightarrow{\alpha'} B \otimes_R M \xrightarrow{\beta'} C \otimes_R M \to 0$$

is exact.

Proof. Since β' is surjective, the sequence is exact at $C \otimes_R M$. We show it is exact at $B \otimes_R M$. Since β is surjective, for every $c \in C$, there exists $f(c) \in B$ such that $\beta(f(c)) = c$. Here f is a set map $C \to B$, which is not uniquely defined in general. Suppose that $\beta(b) = c$. Then $b - f(c) \in \text{Ker } \beta = \text{Im } \alpha$, so $f(c) + \text{Im } \alpha = b + \text{Im } \alpha$. Define a set map by

$$\begin{array}{ccc} g & : & C \times M & \longrightarrow & (B \otimes_R M) \, / \operatorname{Im} \alpha' \\ & & (c,m) & \longmapsto & f(c) \otimes m + \operatorname{Im} \alpha' \end{array}$$

Note that if $\beta(b) = c$, then $b \otimes m - f(c) \otimes m = \alpha(a) \otimes m \in \text{Im } \alpha'$ for some $a \in A$. We can check that g is linear in both arguments. For example, for the first argument, we have $g(c_1 + c_2, m) = f(c_1 + c_2) \otimes m + \text{Im } \alpha'$. Now $\beta(f(c_1 + c_2)) = c_1 + c_2 = \beta(f(c_1)) + \beta(f(c_2)) = \beta(f(c_1) + f(c_2))$ so

$$g(c_1 + c_2, m) = (f(c_1) + f(c_2)) \otimes m + \operatorname{Im} \alpha' = f(c_1) \otimes m + f(c_2) \otimes m + \operatorname{Im} \alpha' = g(c_1, m) + g(c_2, m).$$

Also, we have $g(cr, m) = f(cr) \otimes m + \operatorname{Im} \alpha'$. But $\beta(f(cr)) = cr = \beta(f(c)r)$, so $f(cr) \otimes m + \operatorname{Im} \alpha' = f(c)r \otimes m + \operatorname{Im} \alpha'$. So

$$g(cr, m) = f(c) r \otimes m + \operatorname{Im} \alpha' = f(c) \otimes rm + \operatorname{Im} \alpha' = g(c, rm).$$

By the universal property, there is a unique homomorphism

$$\psi : C \otimes_R M \longrightarrow (B \otimes_R M) / \operatorname{Im} \alpha'$$

$$c \otimes m \longmapsto f(c) \otimes m + \operatorname{Im} \alpha'$$

Next observe that $(\beta' \circ \alpha')(a \otimes m) = (\beta \circ \alpha)(a) \otimes m = 0$, since $\operatorname{Im} \alpha = \operatorname{Ker} \beta$. Since $A \otimes_R M$ is generated by pure tensors, we have $\beta' \circ \alpha' = 0$. So $\operatorname{Im} \alpha' \leq \operatorname{Ker} \beta'$. Hence β' induces a map

$$\phi: (B \otimes_R M) / \operatorname{Im} \alpha' \to C \otimes_R M.$$

It is easy to check that ϕ and ψ are mutually inverse, and so both are isomorphisms. In particular ϕ is injective, and so Im $\alpha' = \text{Ker } \beta'$ as required.

Definition 1.37. A left R-module M is **flat** if $A \to B$ is injective implies that $A \otimes_R M \to B \otimes_R M$ is injective.

If M is flat then any short exact sequence of right R-modules

$$0 \to A \to B \to C \to 0$$

corresponds to a short exact sequence of abelian groups

$$0 \to A \otimes_R M \to B \otimes_R M \to C \otimes_R M \to 0.$$

Proposition 1.38. Every projective module is flat.

This follows from two lemmas.

Lemma 1.39. $P \oplus Q$ is flat if and only if P and Q are both flat.

Proof. Recall there is a canonical isomorphism

$$A \otimes_R (P \oplus Q) \cong (A \otimes_R P) \oplus (A \otimes_R Q)$$
.

Suppose $\alpha: A \to B$ is injective. Then $\alpha': A \otimes_R (P \oplus Q) \to B \otimes_R (P \oplus Q)$ corresponds to

$$\overline{\alpha'} : (A \otimes_R P) \oplus (A \otimes_R Q) \longrightarrow (B \otimes_R P) \oplus (B \otimes_R Q)$$
$$(a \otimes p, 0) \longmapsto (\alpha (a) \otimes p, 0)$$
$$(0, a \otimes q) \longmapsto (0, \alpha (a) \otimes q)$$

It is clear from this that $\overline{\alpha'}$ is injective if and only if $A \otimes_R P \to B \otimes_R P$ and $A \otimes_R Q \to B \otimes_R Q$ are injective, and Lemma 1.39 follows immediately.

Lemma 1.40. Every free R-module is flat.

Lecture 11 is a problems class.

Proof. We know $(A \oplus B) \otimes_R C \cong (A \otimes_R C) \oplus (B \otimes_R C)$. Similarly,

$$\left(\bigoplus_{s\in S} A_s\right) \otimes_R C \cong \bigoplus_{s\in S} \left(A_s \otimes_R C\right).$$

So Lemma 1.39 generalises, so $\bigoplus_{s \in S} A_s$ is flat if and only if all of the A_s is flat for $s \in S$. Let F be free. Then $F = \bigoplus_{s \in S} R$, and so F is flat if and only if R is flat. But for any R-module in A, we have $A \otimes_R R \cong A$, so

$$\begin{array}{ccc} A & \xrightarrow{\quad \alpha \quad \quad } B \\ \mathbb{R} & \\ A \otimes_R R & \xrightarrow{\quad \alpha' \quad \quad } B \otimes_R R \end{array},$$

and it is easy to check that R is flat.

Proof of Proposition 1.38. Lemma 1.39 and Lemma 1.40 imply Proposition 1.38, since a projective module is a direct summand of a free module. \Box

There exist flat modules which are not projective. We will show that \mathbb{Q} as a module for \mathbb{Z} is flat, and it is easy to see it is not projective. To do this we will study the case of modules over a PID.

1.8 Modules over a PID

Recall that R is an **integral domain** if R is commutative and rs = 0 implies that r = 0 or s = 0 for $r, s \in R$. An integral domain is a **PID** if every ideal is $\langle a \rangle = \{ra \mid r \in R\}$ for some $a \in R$.

Example. The ring \mathbb{Z} is an example of a PID.

Proposition 1.41. Let R be a PID. Then every projective R-module is free. Equivalently, every summand of a free module is free.

In fact we will show that any submodule of a free module is free. Moreover, if $F_1 \leq F_2$, where F_1 and F_2 are free, and if B_1 and B_2 are bases for F_1 and F_2 respectively, then $|B_1| \leq |B_2|$. In particular, if $M \leq R^n$, then $M \cong R^m$ for some $m \leq n$. For this, we will need the well-ordering theorem.

Theorem 1.42 (Well-ordering theorem). Let X be a set. There exists a well-order \leq on X, that is a total order such that every non-empty subset of X has a least element.

Corollary 1.43 (Transfinite induction). Let X be a non-empty set well-ordered by \leq . Let x_0 be the least element of X. Let $S \subseteq X$. If $x_0 \in S$, and s < t implies $s \in S$ implies that $t \in S$, then S = X.

Proof. Let $F = \bigoplus_{s \in S} R$. Let \leq be a well-order on S. For $s \in S$, let π_s be the projection map $F \to R$ onto the s-coordinate. Let e_s be the element of F with one in coordinate s, and zero elsewhere. Suppose U is an R-submodule of F. Define R_t to be the submodule of F generated by $\{e_s \mid s \leq t\}$. So if $t_1 \leq t_2$ then $R_{t_1} \leq R_{t_2}$. Let $U_t = U \cap R_t$. So $t_1 < t_2$ implies that $U_{t_1} \leq U_{t_2}$. Consider $\pi_s(U_s)$. This is an ideal of R. Hence there exists $a_s \in R$ such that $\pi_s(U_s) = \langle a_s \rangle$, since R is a PID. For each s, let $u_s \in U_s$ be such that $\pi_s(u_s) = a_s$. In cases where $a_s = 0$, assume $u_s = 0$. Let $B = \{u_s \mid s \in S, u_s \neq 0\}$. Claim that B generates U. We will actually prove that $\{u_s \mid s \leq t\}$ generates U_t , using transfinite induction. If s_0 is the least element of S, it is easy to see that u_{s_0} generates U_{s_0} . Suppose $\{u_s \mid s \leq t\}$ generates U_t for all $t < t_0$. Let $u \in U_{t_0}$. Then $\pi_{t_0}(u) = ra_{t_0}$. Hence $\pi_{t_0}(u - ru_{t_0}) = 0$. So $u - ru_{t_0}$ has zero in the t_0 -coordinate, so $u - ru_{t_0} \in \text{sp}\{e_s \mid s < t_0\}$. Clearly $u - ru_{t_0} \in U$. We have $u - ru_{t_0} = \sum_{i=1}^q r_i e_{s_i}$, where $s_i < t_0$, and $s_1 < \cdots < s_q$. Then $u - ru_{t_0} \in U \cap R_{s_q} = U_{s_q} = \text{sp}\{u_s \mid s \leq s_q\}$ by inductive hypothesis. Hence $u \in \text{sp}\{u_s \mid s \leq s_q\} \cup \{u_{s_{t_0}}\} \subseteq \text{sp}\{u_s \mid s \leq s_{t_0}\}$. Hence $\{u_s \mid s \leq s_{t_0}\}$ generates U_{t_0} , as required. \square
